Total metrics

7

Missing KPIs

7

Topic sections

Green left border = metric MISSING from the dashboard (new KPI) | No coloured border = metric already present in the dashboard

Missing Business KPIs

Metrics not present in the current dashboard - critical for financial performance assessment

[NEW] Revenue / GMV (Gross Merchandise Value)

MISSING from dashboard

Formula:

$GMV = \text{Total value of all orders placed in a given period (gross, before deducting returns)}$

$\text{Revenue} = \text{GMV minus returns, cancellations and discounts}$

What it measures:

The most important business metric in e-commerce - answers the question: how much money did the website generate? GMV is the gross value of all orders. Revenue is net income after deducting returns. Without this metric, the entire dashboard describes user behaviour but says nothing about financial results. For a multi-brand store, GMV should be broken down by brand, category, country and channel.

Example / How to read:

Example: In March, 5,000 orders were placed with an average basket value of 300 EUR - $GMV = 1,500,000$ EUR. Even if the ATC rate increased by 2%, without GMV you do not know whether that translated into more money.

Benchmark / What to do:

What to monitor: Total GMV | GMV by brand | GMV by category | GMV online vs offline | GMV trend week-over-week and year-over-year (YoY). YoY change is more important than the absolute value - seasonality in home appliances is significant.

[NEW] Overall Conversion Rate

MISSING from dashboard

Formula:

$\text{Conversion Rate} = \text{Number of orders} / \text{Number of all visits} \times 100$

What it measures:

The most important efficiency metric for the entire store - what percentage of all visits result in a purchase. It is the final score of the entire funnel: traffic -> interest -> basket -> payment. IMPORTANT DISTINCTION: Purchase Intent Rate (which is in the dashboard) is NOT the same - it measures intent, not transaction completion. You can have 15% Purchase Intent and only 1.5% Conversion Rate - because many users drop off at the checkout stage.

Example / How to read:

Example: 500,000 visits per month, 5,000 orders -> $CR = 1\%$. If you improve CR to 1.2% without changing traffic = 1,000 additional orders per month. That is why CR is more important than traffic volume.

Benchmark / What to do:

Home appliance e-commerce benchmarks: Good: 1.5-3% | Average: 0.8-1.5% | Poor: below 0.8%. Appliances have a lower CR than clothing (buying a washing machine is a big decision), but a higher basket value. Always analyse CR together with AOV.

[NEW] Average Order Value (AOV)

MISSING from dashboard

Formula:

$$\text{AOV} = \text{Total Revenue} / \text{Number of orders}$$

What it measures:

How much the average customer spends in a single order. A simple but very powerful metric - increasing AOV by 10% with the same number of orders = +10% Revenue without any additional marketing spend. AOV is influenced by: cross-sell (add accessories), upsell (more expensive model), bundle (product sets), Additional Service Attach (installation, warranty). That is why AOV and Additional Service Attach rate should be tracked together.

Example / How to read:

Example: Customer buys a washing machine for 600 EUR. If they also add installation (80 EUR) and extended warranty (100 EUR) - AOV increases from 600 to 780 EUR = +30% Revenue without any new customer.

Benchmark / What to do:

What to monitor: Overall AOV | AOV by category (fridges vs vacuums) | AOV by channel (mobile vs desktop) | AOV by country | AOV trend - is it growing after introducing cross-selling? Warning signal: if AOV drops while order count rises - you may be acquiring customers for cheaper products.

[NEW] Traffic Sources

MISSING from dashboard

Formula:

$$\text{Channel share} = \text{Visits from a given channel} / \text{All visits} \times 100$$

What it measures:

Where users come from. Each traffic source has different characteristics - different bounce rate, conversion rate and basket value. Without this metric you do not know where to spend the marketing budget. Main channels: Organic Search (Google without paying), Paid Search (Google Ads - you pay per click), Direct (typed the address directly or bookmarked), Email (newsletter, email campaign), Social (Facebook, Instagram, YouTube), Referral (link from a comparison site or blog), Display/Retargeting (remarketing banners).

Example / How to read:

Example why this is critical: A bounce rate of 49.8% may be normal if 40% of traffic comes from Paid Search (ads attract less engaged users). But if bounce is high mainly in Organic - that is a problem with SEO and page content, because organic should attract more targeted users.

Benchmark / What to do:

What to analyse per channel: Visits | Bounce rate | Conversion rate | AOV | Revenue. If Paid Search has CR 0.5% but Email has CR 4% - the email budget is significantly more efficient. You cannot see this without breaking down by source.

[NEW] Conversion Rate per Device

MISSING from dashboard

Formula:

$CR \text{ per device} = \text{Orders from a given device} / \text{Visits from that device} \times 100$

What it measures:

A separate conversion rate for each type of device: mobile phone, desktop (computer), tablet. This is one of the most important analyses in e-commerce, because mobile and desktop are often completely different user experiences with completely different purchasing behaviours. The dashboard shows that Mobile Phone dominates traffic - but without this metric you do not know whether mobile also dominates sales.

Example / How to read:

Typical home appliance scenario (cross-device journey): Customer sees a washing machine ad on their phone - browses specifications on mobile - returns in the evening on desktop - buys on the computer. If you measure only one channel, mobile looks poor (lots of traffic, low conversion), while desktop looks great - but in reality mobile was the first step in the purchase funnel.

Benchmark / What to do:

Home appliance benchmarks: Mobile: 0.5-1.2% CR (research, not purchase) | Desktop: 1.5-3.5% CR (purchase completion) | Tablet: approx. 1-2%. If mobile CR is very low (below 0.5%) - priority: simplify mobile checkout, improve loading speed, Apple Pay / Google Pay.

[NEW] New vs Returning Visitors - Conversion Rate

MISSING from dashboard

Formula:

$CR \text{ new} = \text{Orders from new users} / \text{Visits from new users} \times 100$

$CR \text{ returning} = \text{Orders from returning} / \text{Visits from returning} \times 100$

What it measures:

Comparison of purchasing effectiveness of new users (first visit to the site) vs returning users (visited before). A fundamental analysis for strategic decisions: invest in acquiring new customers (acquisition) or retaining existing ones (retention)? The dashboard already measures Returning Visitors rate and Registration rate - but without CR you do not know whether returners actually buy more.

Example / How to read:

Typical home appliance scenario: New users: CR 0.4% - they arrive, browse, leave (research phase 1). Returning users: CR 3.2% - they return to buy (decision made). Conclusion: returning users convert 8x better - worth investing in retention tools (email, loyalty programme, wishlist) to retain the user and bring them back.

Benchmark / What to do:

High CR for new users: site converts cold traffic well, acquisition campaigns are effective. Low CR new, high returning: typical for appliances - invest in remarketing, email automation, push notifications after 1st visit. Low CR for both groups: fundamental problem (price, UX checkout, product availability).

[NEW] Cross-sell / Upsell Rate

MISSING from dashboard

Formula:

Cross-sell rate = Orders with ≥ 2 different product categories / All orders $\times 100$

Upsell rate = Orders with a higher-tier product than originally viewed / All orders $\times 100$

What it measures:

Cross-sell = customer bought a washing machine AND detergent / accessories / extension cable. Selling products from a different category alongside the main purchase. Upsell = customer viewed a washing machine at 500 EUR but bought the 700 EUR model after seeing the recommendation 'Customers also choose...'. Selling a more expensive variant of the same product. The dashboard already has Additional Service Attach rate (narrow cross-sell of services). A full product cross-sell metric is missing.

Example / How to read:

Examples for a home appliance store: Cross-sell: Buying a dishwasher -> Add dishwasher salt + tablets. Upsell: Viewing a Samsung 400L fridge -> 'See the 500L model with No Frost - only 100 EUR more'. If cross-sell rate = 8% and AOV with cross-sell is 35% higher -> cross-sell generates real revenue.

Benchmark / What to do:

E-commerce benchmarks: Cross-sell rate: 10-30% (Amazon achieves approx. 35%) | Upsell rate: 5-15%. How to improve: 'Customers also bought' section on PDP and in basket, recommendations based on browsing history, product bundles ('Washing machine + dryer set -10%'), dynamic pricing upsell in checkout.

User Engagement

Metrics measuring how actively users engage with the website

Time spent per visit

Present: 369 sec (~6 min)

Formula:

Total time on site / number of visits

What it measures:

Average number of seconds a user spends during a single visit to the website. 369 sec = approx. 6 minutes. Measures overall engagement - the more time spent, the more the user is drawn into browsing and research. For home appliances, 6 minutes is a good result - customers read specifications, compare models, browse photo galleries.

Example / How to read:

General e-commerce benchmark: 3-4 min. 6 minutes is above average. Low time may mean the page does not meet user needs or loads too slowly. Monitor alongside bounce rate.

Benchmark / What to do:

Good result for home appliances: > 5 minutes. Low result (< 2 min) = problem with content quality or page speed. If time is high but conversion is low - users are engaging but something blocks them from purchasing (price, availability, checkout).

Bounce rate

Present: 49.8%

Formula:

Visits with only 1 pageview / all visits x 100

What it measures:

Percentage of visits where the user viewed only one page and left the site without any interaction. Nearly every other visit ends after viewing just one page. Not all bounces are bad - if a user found a phone number and called, that is also a bounce but a good outcome.

Example / How to read:

For home appliances with traffic from ads and comparison sites, benchmark is 45-60%, so 49.8% is within normal range. Would be concerning above 65-70%. Always analyse in the context of traffic source: paid search naturally has a higher bounce rate than direct or email.

Benchmark / What to do:

Benchmark: Home appliances 45-60% OK | > 65% concerning | > 75% alarming. Always analyse together with the traffic source. Most important question: which pages have the highest bounce rate and why?

Bounce Rate - Based on Single Page Visits

Present: 58% (alternative method)

Formula:

Single-page sessions / all sessions x 100

What it measures:

Alternative definition of bounce rate - based on sessions with only one pageview. Differs from the standard Adobe bounce rate in its methodology for counting sessions vs visits. The dashboard shows 3 different bounce values (49.8%, 58%, 50.14%) - the same idea measured by different methods. An 8 pp difference between methodologies is normal.

Example / How to read:

The problem arises when in a meeting someone asks what is our bounce rate and gets 3 different answers. Choose one definition and stick to it consistently throughout all reporting.

Benchmark / What to do:

Recommendation: choose one official definition for reporting, mark the others as alternative methodology (for reference). Add a tooltip explaining the difference.

Feedback Intent Activation rate

Present: definition

Formula:

Visits with a click on the feedback module / visits that opened the module x 100

What it measures:

Measures how often users who were shown a feedback module (e.g. Rate this page button, NPS survey) actually click on it and express an opinion. Measures the effectiveness of the user feedback collection system.

Example / How to read:

Low value = module is ignored (poor placement, poor timing, no motivation). High = feedback collection system works effectively and users are willing to share their opinion.

Benchmark / What to do:

Important for the UX Research team - allows assessing whether collected opinions are representative (high activation = broad sample) or selective (low activation = only very satisfied or dissatisfied users respond).

Users & Traffic

Metrics describing who the users are and how they reach the site

Returning Visitors rate

Present: definition

Formula:

$\text{Visitors with } >1 \text{ visit} / \text{all unique visitors} \times 100$

What it measures:

What percentage of unique users visit the site more than once. Measures loyalty and the habit of returning to the store. For home appliances, the purchase cycle lasts weeks - a customer returns several times before deciding to buy a washing machine or fridge. High returning rate = good retention and brand recognition.

Example / How to read:

Worth comparing returning vs new in the context of conversion - returners usually convert significantly better (3-8x) than new users. The number of returns alone without conversion data does not give the full picture.

Benchmark / What to do:

Pair with the new New vs Returning CR metric. If returning rate is high but CR is low - returners come back to browse, not buy. This is an important distinction for strategy.

Returning Visitors registration rate

Present: definition

Formula:

$\text{Registered returning users} / \text{all returning users} \times 100$

What it measures:

What proportion of returning users are registered (have an account in the store). Measures whether loyal visitors are also identified by the system - which enables personalisation and email targeting.

Example / How to read:

Low value = a large portion of returners are anonymous - the store cannot target them by email or personalise their experience. High = good base of registered customers for re-engagement and marketing automation.

Benchmark / What to do:

If returning rate is high but registration rate is low - worth investigating registration barriers. Perhaps the form is too long, required too early, or there are no clear benefits of having an account.

Registration rate after first visit

Present: definition

Formula:

Returners who registered after 1st visit / those who did not register during 1st visit x 100

What it measures:

Measures the effectiveness of delayed registration - users who did not register during their first visit but did so on a subsequent visit. Shows whether the store effectively encourages registration upon return.

Example / How to read:

Helps assess whether an email reminder to complete registration, a message at login, or an exclusive offer for registered users works. If low - check whether there is any trigger encouraging registration on return.

Benchmark / What to do:

Best practice: send an email 24-48h after the first visit highlighting registration benefits (order tracking, history, faster checkout, exclusive offers).

Most visited product categories

Present: top 10 visible

Formula:

Number of visits to pages of a given category in the selected period

What it measures:

Ranking of the 10 most frequently visited product categories (Feb-May). Shows what customers are most interested in - regardless of whether they bought. Top categories visible: fridgefreezers, washingmachines, rechargeablefloorvacuumcleaners, cookersandovens, builtindishwashers, inductionandelectrohobs, cookerhoods, freestandingdishwashers, cookingbakingovens, tumbledryers. Heavy home appliances dominate.

Example / How to read:

Important for prioritisation: these categories should have the best-optimised PDPs, fastest page loading, best filters and the highest photography and content budget.

Benchmark / What to do:

Note: category names are concatenated (fridgefreezers instead of Fridge Freezers) - an analytics implementation artefact. For presentations and reports, use readable labels.

Visits by device type

Present: data visible

Formula:

Visits from a given device / all visits x 100

What it measures:

Traffic breakdown by: Mobile Phone, Other (= desktop), Tablet, Television, Set-top Box, Media Player, Gaming Console, EReader. Desktop is hidden under the Other category. Mobile Phone dominates significantly, desktop second, tablet marginal.

Example / How to read:

Key question: does mobile also dominate in sales or just in browsing? Without Conversion Rate per Device you cannot answer this. Typical home appliance cross-device journey: research on mobile -> purchase on desktop.

Benchmark / What to do:

If > 60% of traffic is mobile - the site must be optimised for mobile first: speed, button sizes, simplified checkout, Apple Pay / Google Pay.

Product Discovery & Navigation

Metrics describing how users find and browse products

Add-to-cart rate (ATC)

Present: definition

Formula:

Visits with ≥ 1 add-to-cart / all visits x 100

What it measures:

Percentage of all visits where the user added anything to the basket. The first strong signal of purchase intent - the user stops browsing and starts considering. A key transition point in the purchase funnel.

Example / How to read:

Home appliance benchmark: 3-8%. Low value may mean: too hard to find the ATC button, product out of stock, deterring price vs competition, or poor images and descriptions on PDP.

Benchmark / What to do:

Monitor ATC rate alongside Cart Abandonment - high ATC + high Abandonment = customers want to buy but something blocks them at the finalisation stage (checkout, delivery, payment methods).

Purchase intent rate

Present: definition

Formula:

$(ATC + \text{dealer search} + \text{buy online click} + \text{external retailer click}) / \text{all visits} \times 100$

What it measures:

Aggregate of all purchase signals in a single visit. Broader than ATC - also includes those who search for a physical store or click to an external retailer. Measures overall purchase readiness in a given period.

Example / How to read:

If Purchase Intent $\gg$ ATC rate - many customers prefer to buy elsewhere rather than online. Worth checking the split between buy online and external retailer to understand channel preferences and inform omnichannel strategy decisions.

Benchmark / What to do:

Compare Purchase Intent rate with Overall Conversion Rate - a large gap between them means a lot of intent leaks without finalisation. This is where to look for checkout problems.

Buy online click rate

Present: definition

Formula:

Visits with Buy online click / all visits x 100

What it measures:

How many visits end with a click on the Buy online button - i.e. direct purchase intent through the e-commerce channel, not through a dealer. Distinguishes online customers from those looking for a physical store.

Example / How to read:

If the buy online rate grows - e-commerce is gaining importance in the sales mix. The trend over time is more important than the absolute value. Compare with external retailer click rate.

Benchmark / What to do:

Important for strategy: if external retailer >> buy online - the own online store may be more expensive or less convenient than partners. Worth investigating why customers prefer buying from dealers.

External retailer click rate

Present: definition

Formula:

Visits with a click to an external retailer / all visits x 100

What it measures:

How many visits end with a redirect to an external trading partner (e.g. Currys, Amazon, John Lewis). Measures how much traffic is sent to partners. Key for the multi-channel model.

Example / How to read:

High value = customers prefer to buy from a dealer rather than directly. Can be strategically desirable (omnichannel) or a problem (own online store is unattractive). Compare with buy online click rate.

Benchmark / What to do:

The trend of this metric over time shows whether the direct-to-consumer strategy is gaining or losing ground. Important for long-term business decisions about sales channels.

Comparison conversion lift

Present: definition

Formula:

CR (with comparison tool) - CR (without comparison tool) = lift in percentage points

What it measures:

By how many percentage points do users of the product comparison tool convert higher than those who do not use it. Lift = the conversion increase resulting directly from using a given feature.

Example / How to read:

If lift = +5 pp - the comparison tool genuinely helps in purchasing decisions and should be prominently displayed on PLP and PDP. If lift is close to zero - it is used by already-decided customers (correlation, not causation).

Benchmark / What to do:

Interpretive caution: high lift may result from selection bias (more decided customers tend to compare), not from the tool effectiveness. For certainty, run an A/B test hiding the tool for a control group.

Filter/sort conversion lift

Present: definition

Formula:

$CR \text{ (with filters/sorting)} - CR \text{ (without)} = \text{lift in percentage points}$

What it measures:

By how much higher do users who use filters or sorting on the product listing (PLP) convert vs those who do not. For home appliances with hundreds of products, good filtering is absolutely critical for user experience.

Example / How to read:

High lift = filters help with selection and genuinely aid conversion. Low lift = filters may be too hidden, too complex or unintuitive. If only 5% of PLP users use filters - they are too hard to access.

Benchmark / What to do:

Also check which filters are used most frequently (energy rating, price, brand, capacity) - this informs how the category page should be structured and which filters should be most prominent.

Competence-to-PDP CTR

Present: definition

Formula:

$\text{Visits going from Competence page to PDP} / \text{all visits to Competence page} \times 100$

What it measures:

CTR (Click-Through Rate) from competence pages - educational or category pages (e.g. How to choose a washing machine, Fridge buying guide) to a specific product card (PDP). Measures the effectiveness of educational content as a sales tool.

Example / How to read:

High CTR = educational content effectively leads to specific products. Low = users read guides but do not go to products - missing visible CTA links like See recommended washing machines.

Benchmark / What to do:

Competence pages typically have higher SEO potential (long-tail keywords) - if they convert well to PDP, it justifies investing in creating more educational articles for the most popular categories.

PLP-to-PDP CTR

Present: definition

Formula:

$\text{Visits going from product listing (PLP) to product page} / \text{all PLP visits} \times 100$

What it measures:

How many visits on the product listing page (category page with product tiles) end with a click on a specific product. This is the entry point to the sales funnel - if there is a problem here, the entire subsequent funnel suffers.

Example / How to read:

Low value = problem with the listing. Possible causes: too many products without good sorting, poor tile images, no price on the tile, slow loading, unclear product hierarchy.

Benchmark / What to do:

Check CTR for different categories - washing machines may have CTR 25% while vacuums 8%. This will indicate where the listing needs work. A/B test different tile layouts, image sizes and price visibility.

Product Discovery Success rate

Present: definition

Formula:

$$\text{PDP visits with ATC OR } \geq 30 \text{ sec on page} / \text{all PDP visits} \times 100$$

What it measures:

Whether a visit to a product page ended in success - either adding to basket or spending at least 30 seconds (a signal of genuine interest, not accidental landing). Two definitions of success in one metric.

Example / How to read:

Practical measure of PDP quality. Low result = users land on PDP and immediately leave - the page does not engage. Worth comparing between categories: do fridges have a higher success rate than vacuums?

Benchmark / What to do:

If success rate grows but ATC does not - users are engaging (spending time) but not adding to basket. The problem may be in the price, availability, lack of an ATC button, or a weak call-to-action.

Product Page - PDP Experience & Content Performance

Metrics measuring the quality and effectiveness of product pages

PDP-to-ATC rate

Present: definition

Formula:

$$\text{PDP visits with } \geq 1 \text{ add-to-cart} / \text{all PDP visits} \times 100$$

What it measures:

The most important quality metric for a product page - how many visits to the product card end with it being added to the basket. A direct measure of the PDP effectiveness in convincing the user to purchase.

Example / How to read:

Home appliance benchmark: 5-15%. Low value may mean: poor product presentation (no images, no video), price too high vs competition, no visible ATC button, too few customer reviews, or out of stock.

Benchmark / What to do:

Compare PDP-to-ATC by category and by brand. If Brand X washing machines have 12% and Brand Y 4% - the problem is the PDP content, price or availability for Brand Y, not the entire store.

Media Engagement rate

Present: definition

Formula:

$$\text{PDP visits with gallery interaction (click, image scroll, video play)} / \text{all PDP visits} \times 100$$

What it measures:

How many visits to a product page end with interaction with the image gallery or video. Measures whether users engage with visual materials. For home appliances, the gallery is the physical store online - the customer cannot touch the product.

Example / How to read:

Low value = gallery is unattractive or not visible. Maybe: too few images, bad format (too small, no zoom), no 360 video, gallery below the fold (users do not see it without scrolling).

Benchmark / What to do:

Check Media Engagement rate for products with video vs without video - if there is a large difference in ATC rate, it justifies investment in video production for key categories.

Reviews reading rate

Present: definition

Formula:

$$\text{PDP visits with a click on the reviews section} / \text{all PDP visits} \times 100$$

What it measures:

How many visits to a product page end with clicking on the customer reviews section. Measures the need for social proof before making a purchasing decision.

Example / How to read:

High rate = customers need reviews before deciding - worth investing in actively collecting opinions (post-purchase email, QR on product). Low may mean: reviews visible without clicking, or no reviews (nothing to read).

Benchmark / What to do:

If Reviews reading rate is high but the number of reviews is small (less than 5) - customers are looking for reviews and not finding them, which may block the purchase. Priority: collecting opinions for the most popular products.

Technical data filtered rate

Present: definition

Formula:

$$\text{PDP visits using search in technical specs} / \text{visits that opened specifications} \times 100$$

What it measures:

How often a user uses the internal search in the product technical specifications section. Measures how hard it is to find a specific specification in the data table (e.g. searching for drum capacity instead of scrolling through 50 parameters).

Example / How to read:

High rate = specification table is too long or disorganised. UX signal: group specifications thematically (Dimensions, Performance, Energy Consumption), highlight key parameters at the top, hide rarely searched ones at the bottom.

Benchmark / What to do:

Check which parameters users search for most frequently - this informs the information hierarchy on the PDP. For a washing machine, key specs: capacity, energy rating, spin speed. Ensure these are visible without scrolling.

Document downloaded rate on PDP

Present: definition

Formula:

$\text{PDP visits with document download} / \text{all PDP visits} \times 100$

What it measures:

How many visits to a product page end with downloading a document - user manual, technical data sheet, energy certificate, PDF specification, CE declaration of conformity. Measures the need for detailed technical information.

Example / How to read:

Particularly important for the B2B segment and installers and technicians. Low value may mean documents are hidden too deep on the page (e.g. in a More information tab without clear labelling).

Benchmark / What to do:

If download rate is high for specific categories (e.g. built-in dishwashers) - these products are bought by professionals (installers). Consider creating a dedicated B2B view with easy access to technical documentation.

Search - Search Experience

Metrics evaluating the effectiveness of the store's internal search engine

Search Zero-results rate

Present: 0.00% - excellent result!

Formula:

$\text{Searches with no results} / \text{all searches} \times 100$

What it measures:

Percentage of searches that returned no results. Measures the dead zone of the search engine - queries the engine does not understand or products not in the catalogue. 0.00% is an outstanding result.

Example / How to read:

0% = the search engine handles every query. Worth checking: is this due to good NLP (engine understands synonyms, typos, natural language queries) or a fallback mechanism showing anything instead of an empty page - as these two scenarios have different implications for result quality.

Benchmark / What to do:

Benchmark: < 5% good | < 2% very good | 0% outstanding or fallback. Monitor what queries historically gave zero results and whether they were resolved by new products or by improving the algorithm.

Search Refinement rate

Present: 53.5% - too high!

Formula:

Visits with a subsequent search after the first / all visits with search x 100

What it measures:

More than half of users using the search engine need to search again - either because the first results are poor, or because they are exploring the catalogue. A high value is a serious signal of relevance problems with search results.

Example / How to read:

53.5% is too much - a good search engine benchmark is below 35%. First diagnosis: check the top 20 queries with the highest refinement rate and assess whether the first-page results are relevant. May be missing autocomplete or Did you mean suggestions.

Benchmark / What to do:

In combination with Search-to-PDP CTR 29.6%: those who find what they are looking for find it well, but more than half need to try multiple times. This suggests a problem with the precision of initial results, not the search architecture itself.

Search-to-PDP CTR rate

Present: 29.6%

Formula:

Visits where user searched and directly went to a PDP / all visits with search x 100

What it measures:

How many visits with search end with a direct transition to a product page without additional clicks through PLP. Measures the precision of the search engine in delivering specific products (not just a results list).

Example / How to read:

29.6% is a decent result - nearly one in three search sessions leads directly to a PDP. Combined with 53.5% refinement: those who find - find well, but many need to try multiple times before landing on the right product.

Benchmark / What to do:

Increasing Search-to-PDP CTR alongside a decreasing Refinement rate = search engine improvement. Monitor these two metrics together as a pair - together they say more than each individually.

Basket & Purchase - Cart Intent & Pre-Checkout

Metrics tracking user behaviour from adding to basket to purchase completion

Cart Abandonment rate

Present: definition

Formula:

Visits with ATC but no purchase / all visits with ATC x 100

What it measures:

What percentage of users who added a product to the basket did not complete the purchase. Measures the leakage at the stage between the decision (ATC) and payment (completion). One of the most frequently monitored indicators in e-commerce.

Example / How to read:

Home appliance benchmark: 70-85% is normal, as customers use the basket as a wishlist and return after a few days. Concerning is an increase over time or large differences between brands (one brand 65%, another 90%).

Benchmark / What to do:

Monitor alongside Error-to-intent rate - distinguish deliberate abandonments (customer wants to think) from error abandonments (technical problem prevented purchase). The latter is a priority to fix.

Cart View Ratio per visitor

Present: definition

Formula:

Total number of basket views / number of unique visitors with ATC

What it measures:

How many times the average user with at least one ATC viewed their basket. Measures how many times they check the basket before buying or abandoning - an indicator of decision hesitation.

Example / How to read:

High value = users repeatedly return to the basket but do not buy. May indicate: uncertainty about the price (looking for a better deal), waiting for a promotion, wanting to consult with family, indecision between products.

Benchmark / What to do:

Good signal for remarketing - these users are hot leads. Worth sending an email reminder about basket products and potentially a time-limited offer such as Other customers are viewing this product.

Error-to-intent rate

Present: definition - CRITICAL metric

Formula:

Visits with ATC that encountered a basket error / all visits with ATC x 100

What it measures:

What percentage of purchase sessions (with add-to-cart) encounter technical errors related to the basket - e.g. product does not add, price does not update, error at checkout transition, product disappears from basket. Every error = a potentially lost transaction.

Example / How to read:

Even 1% with high traffic is enormous losses: with 1M visits and 5% ATC rate = 50K purchase sessions. If Error-to-intent = 2% = 1,000 visits with basket errors = tens of thousands in lost revenue monthly.

Benchmark / What to do:

Absolute priority for the tech team - fix basket errors before everything else. Configure an alert that immediately notifies when Error-to-intent exceeds 1%. Check errors by device (mobile may have more errors than desktop).

Return after ATC no order rate

Present: definition

Formula:

Visitors with ATC but no purchase who returned in a subsequent visit / all with ATC but no purchase x 100

What it measures:

How many users who abandoned their basket (added products but did not buy) returned to the site in a subsequent session. Measures the remarketing potential of warm leads - people who are in the purchase process but need more time.

Example / How to read:

Key for home appliances where decisions take weeks. High value = large pool of customers in the decision process - worth reaching them with a basket abandonment email, push notification, or retargeting with the product they abandoned.

Benchmark / What to do:

Benchmark: returns within 7 days are most valuable - purchase within a week of basket abandonment is the typical cycle for home appliances. Email automation: email 1h after abandonment + 24h + 7 days = standard recovery flow.

Return and buy after ATC no order rate

Present: definition

Formula:

Visitors with ATC but no purchase who returned AND completed a purchase / all with ATC but no purchase x 100

What it measures:

How many of those who abandoned their basket ultimately bought during a subsequent visit. Measures the effectiveness of purchase decision maturation - how many abandonments are actually delayed purchases. Together with the previous metric creates the full picture: how many return vs how many of them actually buy.

Example / How to read:

Typically high for home appliances (long purchase cycle). If many return (high Return after ATC) but few buy upon return (low this metric) - what is blocking them on return? Maybe the price changed, product is out of stock, or checkout is too complex.

Benchmark / What to do:

Monitor the trend of this metric after changes in checkout or remarketing strategy - a direct indicator of the effectiveness of basket abandonment recovery actions.

Return and buy same visit over return after ATC no order rate

Present: definition - complex metric

Formula:

Returners with ATC but no purchase who bought in the same return session / all returners with ATC but no purchase x 100

What it measures:

Among those who returned after abandoning their basket - how many bought immediately upon return (in the same session). Distinguishes: returned and bought immediately (decision made, returned to finalise) vs returned but browsed again and left.

Example / How to read:

If high - return is a strong signal of decision (I came back to buy). You can then show a simplified checkout or product reminder upon return. If low - returners are still hesitating.

Benchmark / What to do:

Helps optimise the return experience: upon returning to the site, do you immediately show the basket with products? Is there a special offer Welcome back, your products are waiting? This can significantly increase this metric.

Additional Service Attach rate

Present: definition

Formula:

Orders with >=1 additional service / all orders x 100

What it measures:

How many completed orders include at least one additional service: appliance installation, extended warranty beyond statutory, old appliance recycling service, configuration and commissioning, door-to-door service. A service cross-selling metric.

Example / How to read:

Key for margin - services often have a higher profit percentage than the hardware. Washing machine installation may have a 60% margin, while the appliance itself 15%. If the rate is low: the service offering may not be visible in checkout, the price may be too high.

Benchmark / What to do:

Compare with AOV - orders with an additional service should have a higher AOV. Check at which checkout step users abandon services (if they added then removed). Test: change the order in which services are presented in checkout.

Most abandoned products - table

Present: table visible

Formula:

Columns: Orders | Cart Additions | First Cart Addition | Cart gap | Cart Abandonment Rate | Cart Abandonment rate - product

What it measures:

Table showing top products with the highest basket abandonment rate. Cart gap = difference between the number of basket additions and number of orders for a specific product. Identifies products that customers want but do not buy.

Example / How to read:

A product with 500 Cart Additions and 50 Orders has a Cart gap of 450 and a Cart Abandonment rate of 90%. This is a red flag: either the price is too high vs competition, there are technical issues, or availability is poor.

Benchmark / What to do:

Action plan for products with the highest Cart gap: check price vs competition (comparison sites), check availability (may be frequently out of stock), check reviews (may have poor ratings), check for technical errors for this SKU.
